30896
S/180/61/000/005/006/018
E194/E555

The metallic body is displaced from a region of strong field to one of weak field, or, as it were, rolls down a 'hollow' in the field. Inductors for melting levitated metals may be classified into three types according to the relationship between the power transmitted to the body and the power applied to the inductor. One type consists of two co-planar rings connected in parallel with currents flowing in opposite directions. In a particular case the rings were of 120 and 210 mm internal diameter and the suspended metal was a disc of 150 mm diameter weighing 460 g. The outer coil was used to stabilise the disc. As the disc moves vertically the field at its surface remains constant; it is horizontal at the lower surface and zero at the upper because the disc thickness is much greater than the depth of penetration of the field. Thus the power applied to the body should remain constant and this is in fact found to be the case. The second type of inductors are those shaped like a boat or cradle consisting of two vertical coils connected in parallel and shaped like a cradle. The ends of the inductor are bent vertically upwards to make the suspended cylindrical body stable in the axial direction. With an inductor of this

Card 6/ 12

Inductors for heating and melting . . .

3096

S/180/61/000/005/006/018

E194/E555

type an increase in the power applied to the inductor reduces the power absorbed by the body. Only after the body has risen a considerable distance above the lower conductors is there an appreciable increase in the power intake of the metal. The third type of inductor again has two vertical loops but one is cross-connected, so that whereas in the second type the upper pair of conductors both carry current in the same direction, in this type diametrically opposite conductors carry current in the same direction. In this type of inductor the metal body undergoes symmetrical compression by the electromagnetic field. As the power applied to the inductors is increased, the field intensity at the body surface increases on all sides and so the transmitted power increases. Comparison of test results for similar specimens at a frequency of 2 500 c/s shows that for a given power applied to an inductor of this cross-connected type, the maximum power transmitted to the body is at least four times greater than that of the 'cradle' type. Thus the cross-connected type should be used to produce high temperatures. The design of inductors for melting metals in the levitated condition has special features.

Card 7/12

Inductors for heating and melting

30896
S/180/61/000/005/006/018
E194/E555

In suspending a liquid body it is necessary that the hydrostatic pressure should be equalised by the electromagnetic at every point of the surface. The weight of suspended liquid metal is limited by its surface tension and specific gravity. To increase the efficiency of the system the size of the inductor should be quite small and to avoid the liquid metal sticking to the inductor conductors the field must be symmetrical. The current-carrying leads distort this symmetry and weaken the field in places. To restore the symmetry various devices are used, such as false leads placed opposite the real ones or displacement of the centres of the upper and lower rings of the inductor, and so on. It is desirable that the bottom of the inductors should be at equal potentials, otherwise the metal at the bottom of the inductor will initially short-circuit the portions at different potential, which can cause sparking and contamination of the hot metal by copper from the inductor. A special 'boat' type of construction is used to set up an equipotential bottom. As before, increasing the power applied to the inductor reduces the power transmitted to the molten metal and this somewhat limits its field of application.

Card 8/12

Inductors for heating and melting . . .

30896
S/180/61/000/005/006/018
E194/E555

The boat-type inductor is very convenient for series melting but the maximum temperature of the molten metal is lower than in a cross-connected inductor. In experiments with the 'boat' construction at a frequency of 70 kc/s, the metal could be raised to a temperature of 1500°C, and at a frequency of 200 kc/s to 2000°C. Therefore, as previously mentioned, the cross-connected inductor should be used to obtain higher temperatures. Two types have been developed, one with the coils connected in parallel and the other connected in series. In neither type is it possible to develop an equipotential bottom as in the boat conductor. However, the low voltage on the lower coil and the high contact resistance between the inductor conductors and the still cold solid metal practically prevents sticking of the metal to the inductor. At the instant of switching-on, the metal jumps and hangs in the field. In the inductor with parallel-connected coils the maximum potential difference between conductors is less than in that with series coils and, therefore, the parallel construction is more reliable in operation. However, the series connection can give higher temperatures. The limiting temperature for an inductor

Card 9/12

30896

Inductors for heating and melting S/180/61/000/005/006/018
 E194/E555

with parallel cross-connected coils at a frequency of 200 kc/s was 2500°C and for the series version 3000°C. This difference arises partly from heavier losses in the leads to the parallel case and partly from the higher magnetic pressure above the suspended metal body in the series case. In the latter the current is the same in both turns whereas in the parallel connection the current in the upper turn is less than that in the lower because of the difference in diameter. The following table gives data on the melting of various metals in inductors of different designs and the weight of the samples.

| Metal | Density g/cm ³ | Melting point, °C | Weight, g | Type of inductor |
|-----------|------------------------------|----------------------|--------------|------------------|
| Titanium | 4.5 | 1720 | 12 | 'Boat' |

TITLE: Superconducting alloy in the Nb-Ga system

SOURCE: Zhurnal tekhnicheskoy fiziki, v. 35, no. 9, 1965, 1675-1677

TOPIC TAGS: superconductivity, superconducting alloy, niobium, gallium

ABSTRACT: Results are presented of measurements of the superconducting properties of alloys in a Nb-Ga system at a temperature of 4.2K and magnetic fields up to 28 kOe. The alloys were prepared by means of special equipment developed by the FTI Laboratory and described elsewhere (I. V. Korkin. Promyshlennoye primeniye tokov vysokoy chastoty, ed. G. F. Golovina, Izd. "Mashinostroyeniye," M-L, 1964, 269-275). The starting materials consisted of vacuum-refined niobium and metallic gallium. The latter was additionally degassed at 800-1000°C in vacuum at 10^{-4} - $2 \cdot 10^{-5}$ mm Hg for a period of 2-3 min. The transition from the superconducting state to the normal state was recorded by a change in the inductance of a coil prepared from the given alloy. Mechanical experiments showed the highest plasticity in alloys with 7-12% Ga (by weight). Their hardness did not exceed 350 kg/mm², whereas the hardness of alloys

Card 1/2

L 2559-66

ACCESSION NR: AP5024050

with 12—32% Ga was 450—850 kg/mm². Alloys containing 7—12% Ga are apparently the most suitable for wires. Orig. art. has: 1 table and 1 figure. [YK] 3

| ABSTRACT: This Author Certificate presents a method for obtaining graft copolymers on the basis of poly-organosiloxanes by the interaction of ionizing radiation with a polyorganosiloxane powder in the presence of modifying additives. To improve the physicochemical properties of the graft copolymers and their thermal stability and solvent stability, imides, e.g., N-substituted imides of maleic acid, are used as modifying additives. The radiation dosage is 0.3--8 Mrad and the intensity of radiation is 0.05--0.7 Mrad per hour. | | | | |

TITLE: The Effect of Conditions of Preliminary Cold Hardening on the Recovery of Cu and its Alloys as a Function of Temperature
(Vliyaniye usloviy predvaritel'nogo naklepa na temperaturnuyu zavisimost' vozvratu medi i yeye splavov)

PERIODICAL: Dokl. 7-y Nauchn. konferentsii, posvyashch. 40-letiyu Velikoy Oktyabr'sk. sots. revolyutsii. Nr 2. Tomsk, Tomskiy un-t, 1957, pp 57-58

ABSTRACT: Investigations were performed in order to establish how temperature and rate of deformation (D) (the degree of D remaining constant) affect the progress of recrystallization curves of Cu and its alloys containing 10 atom-% Ni and Al. It was established that the increase in recrystallization temperature of Cu and its alloys is directly proportional to the degree of D; it is therefore assumed that for each temperature of D there is a corresponding field of D dislocations, the temperature stability of which increases with increasing temperatures of D. It is

Card 1/2

SOV/137-58-10-21531

The Effect of Conditions of Preliminary Cold Hardening (cont.)

pointed out that the temperature stability of the cold-hardening of the Cu-base solid solutions investigated is a function of the nature of the alloy. Compared with Al, the addition of which tends to reduce the strength of cohesive bonds, introduction of Ni increases the cohesive forces in the Cu lattice and results in a greater rate of increase in temperature stability of the work-hardened regions.

TITLE: Intergranular internal adsorption in Cu-Al solid
solutions during quenching from elevated temperatures

PERIODICAL: Fizika metallov i metallovedeniye, v. 12, no. 6,
1961, 927 - 928

TEXT: Since solubility of Al in Cu above 565 °C decreases
with increasing temperature, it was postulated by
V.I. Arkharov (Ref. 1 - Trudy IFM AN SSSR, no.23, 1960, p.87)
that internal intergranular adsorption of Al may take place in
concentrated Cu-Al solid solutions at sufficiently high
temperatures, this phenomenon being associated with the
influence of a so-called "pre-precipitation" factor [Abstracter's
note: "pre-precipitation" is used instead of the term
"preparation to precipitation", which is the literal translation
of the term used in the original]. To check this hypothesis,
the present authors compared internal friction, etching

Card 1/4

S/126/61/012/006/023/023

Intergranular internal adsorption... E193/E383

characteristics, microhardness, lattice parameter and electrical resistance of Cu-Al alloys with 14.3 and 14.9 at.% Al, water-quenched from 900°C or annealed (i.e. slowly cooled from high temperatures). The existence of granular adsorption was clearly indicated by the results of internal-friction measurements reproduced in a figure where

δ^{-1} is plotted against the test temperature of Cu + 14.3 at.% Al (broken curve) and Cu + 14.9 at.% Al (continuous curve) alloys. Curves 1 and 2 relating to annealed, Curves 1' and 2' to quenched specimens. The sharp decrease in the magnitude of the internal-friction peak of quenched alloys is obviously due to increased concentration of Al atoms at the grain boundaries. This conclusion was confirmed by the results of other tests. Thus, whereas there was no difficulty in revealing the grain boundaries of annealed specimens by etching in concentrated HNO_3 , the grain boundaries in quenched specimens

Card 2A

S/126/61/012/006/023/023

Intergranular internal adsorption ... E193/E383

could be revealed only by electrolytic etching. The difference between the microhardness in the interior of the grains and in the grain boundary regions was 29 kg/mm^2 for annealed and 43 kg/mm^2 for quenched specimens. Similarly, the lattice parameter (in the interior of the grains) was 3.6413 \AA in annealed and 3.6406 \AA in quenched Cu-Al alloying with 14.9 at.% Al. Finally, in contrast to specimens quenched from low ($400 - 600^\circ\text{C}$) temperatures, the electrical resistance of alloys quenched from 900°C increased during subsequent heat treatment, provided it was carried out at sufficiently high temperatures and for a sufficiently long time. This increase was no doubt caused by the diffusion of Al atoms from the grain boundaries into the interior of the grains, which provided yet another proof of the authors' theory regarding the possibility of internal intergranular adsorption in alloys of systems such as Al-Cu or Cu-Zn, in which the solid solubility decreases with increasing temperature.

TITLE: Effect of deformation of order-disorder processes in Cu-Al alloys

PERIODICAL: Ukrains'kyy Fizychnyy Zhurnal, v. 8, no. 3, 1963, 359-363.

TEXT: It is known that the existence of close order in alloys may contribute significantly to strengthening of alloy and in changing its deformation properties. This contribution may be evaluated after subsequent annealing of deformed alloy, when the close order is restored. At the same time, ordering process in deformed alloys has a number of peculiarities which are associated with the presence of a large number of dislocations and vacancies in the material. Therefore, study of ordering not only aids the understanding of nature of deformed state, but is of interest in itself. This work is involved with study of these processes in Cu-Al alloys having significant short order. The methods of measuring density, hardness, electrical resistance and temperature dependence of resistance were used to investigate the deformed state of Cu Alloy. It is shown that a small plastic deformation additionally orders the annealed Cu-Al alloy. Ordering is enhanced in the course of a small deformation if the alloy is quenched from high temperatures. The conclusion is

Card 1/2

L 12478-63

S/185/63/008/003/004/009

Effect of deformation of order-disorder processes...

that basic ordering of Cu-Al alloys during deformation is not associated with the presence of short-range order in the alloy. The article contains 2 figures and a 17 item bibliography.

TITLE: The effect of temperature on resistance to deformation in Cu-Al solid
solutions 27 27

SOURCE: Fizika metallov i metallovideniye, v. 19, no. 3, 1965, 477-480

TOPIC TAGS: metal mechanical property, metal deformation, copper alloy, aluminum
alloy 16

ABSTRACT: Alloys of copper with 1.1, 6.0, 10.5, 17.3 and 20.3 at % Al were examined
for the following purposes: 1) to determine the effect of temperature on the
resistance to deformation $\sigma = f(T)$ with gradual increase in the concentration of the
solid solution; 2) to investigate curves for $\sigma = f(T)$ for various degrees of deform-
ation, beginning at the yield point; 3) to determine the effect of grain boundaries
on the temperature relationship $\sigma = f(T)$. Electropolished specimens of these alloys
were tensile deformed in a vacuum at various temperatures at a rate of 1.32%/min.
It was found that the temperature relationship $\sigma = f(T)$ depends strongly on the con-

Card 1/3

L 57811-65

3

centration of the solid solution. In dilute alloys of Cu-Al with 1.1 and 6.0% Al, σ decreases steadily with increase in temperature. However, at $T < 300^\circ\text{C}$ an anomaly is observed in the rate function of the resistance to deformation, believed to be associated with substantial diffusion hardening processes. A detailed study of all the specimens indicated that there are actually two anomalies; a low temperature anomaly (at $T < 300^\circ\text{C}$) and a high temperature anomaly (at $T > 300^\circ\text{C}$). The effect of diffusion hardening processes on the curve $\sigma = f(T)$ was evaluated according to the yield point σ_A which appears during deformation aging of a specimen under loading after deformation. It was found that only the low temperature anomaly was associated with diffusion hardening processes.⁴ It was also found that the grain boundaries in the alloys studied are enriched with atoms of the alloying element which substantially block their migration at moderate temperatures. At higher temperatures, migration of grain boundaries becomes possible. The activation of this process is believed to be determined by the diffusion mobility of Al atoms which make up the segregations along the grain boundaries. Orig. art. has: 2 figures.

TITLE: Synthesis of α -Chlorocarboxylic Acids by Addition of Chlorine in Formic Acid to Compounds Containing the $\text{Cl}_2\text{C}=\text{CH}-$ Group

PERIODICAL: Izvestiya Akademii nauk SSSR. Otdeleniye khimicheskikh nauk, 1959, Nr 12, pp 2122-2125 (USSR)

ABSTRACT: The reaction

is conducted by gradually passing chlorine through a solution of appropriate chloroolefin at 30° . The following acids were prepared in this manner: α, β -dichloro-propionic acid; α -chloro- β -methoxypropionic acid; α -chloro- β -formoxypropionic acid, yield 73%, mp $66-67^\circ$ (from benzene); α -chloro- δ -formoxyvaleric acid, yield

TITLE: Homolytic Addition of Hydrogen Bromide to 1-Fluoro-1,
1-Dichloropropene

PERIODICAL: Doklady Akademii nauk SSSR, 1960, Vol. 132, No. 3,
pp. 606-608

TEXT: The authors determined in their paper the divergent behavior of 1-fluoro-1, 1-dichloropropene in the reaction of the homolytic addition from that of 1,1,1-trichloropropene. Two fluoro-dichloro-bromopropanes were obtained as a consequence of the reaction of the 1-fluoro-1, 1-dichloropropene with HBr at an ultraviolet exposure: 1-fluoro-1, 1-dichloro-3-bromopropane and 1-fluoro-1,2-dichloro-3-bromopropane at a ratio 2:1. The reaction proceeded as chain reaction of free radicals. The addition of HBr to 1,1,1-trichloro-propene leads, under equal conditions, to a single product: 1,1,2-trichloro-3-bromopropane.

USSR/Medicine - Regeneration

11 Oct 49

"Regeneration of an X-Rayed Limb Upon the Transplantation Upon It of Nonirradiated Skin," V. P. Sidorova, Inst of Experimental Biol, Acad Med Sci USSR, 3 pp

"Dok Ak Nauk SSSR" Vol LXVIII, No 5

One series of experiments on axolotls produced regeneration of fore and hind legs, corium and bone structure of which were direct continuations of the stumps. Assumption that regenerations are formed by both transplanted and X-rayed tissue was confirmed by second series of experiments. It appears

151UT2

USSR/Medicine - Regeneration (Contd) 11 Oct 49

that regenerations are formed by the above tissues, regenerative capacity of which is restored while their cellular elements are involved in regenerative process. Submitted by Acad Ye. N. Pavlovskiy, 3 Aug 49.

151UT2

USSR/Biology - Tissue Therapy, Radiology Nov 51

"Regeneration of X-ray Irradiated Extremity of Axolotl on Transplantation of Heteroplastic Tissues,"
V. F. Sidorova, Inst Exptl Biol, Acad Med Sci USSR

"Dok Ak Nauk SSSR" Vol LXXXI, No 2, pp 297-299

V. P. Filatov et al have shown that tissue transplantation brings about regeneration when healing is otherwise slow or does not occur at all. Author imputated right hind extremity of axolotl after both hind extremities had been irradiated with X-rays. The regenerative capacity, which is normally inhibited entirely by prior X-ray treatment, was restored

1953

(Contd)

by implanting near the wound pieces of int organs of the axolotl or muscle tissue of frog. The imputated extremity grew again.

Title : The Effect of Corn Sowing Schedules on the Green Feed Yield

Orig Pub : Tr. Kostromsk. s.-kh. in-ta, 1957, vyp. 1, 31-35

Abstract : At an experimental training farm, the early (May 21-22) periods of sowing corn produced sparse sprouting and a low yield of green stuff. Sowing on June 1 and 8, 1954 and on July 3 and 4, 1956 with the temperature of 14-16° at the depth of the seed hole produced the highest yield of corn green feed in all varieties undergoing the test (Sterling variety up to 680 centners/ha of green feed.)

soils in the Vol'skiy Leskhoz, and on the carbonate rubble soils of the Gorodskoye and Oktyabr'skoye forestry establishments, showed that due to the low fertility of the shallow rubble soils, oak grows more poorly than pine, birch and even ash, but it survives better than these species. Pine and birch form plantations of high grade. It is recommended to give up the pure culture of the oak and introduce pine and birch more widely. On the carbonate, rubby, shallow soils, it is more expedient to introduce first of all the pine and then the birch. It is also expedient to try

SOURCE: Byulleten' izobreteniy i tovarnykh znakov, no. 14, 1965, 62

TOPIC TAGS: metal cutting, plasma arc

ABSTRACT: This Author's Certificate introduces a water-cooled torch for plasma-arc metal cutting. The torch contains a nonconsumable tungsten electrode and a shaping nozzle. The durability of the nozzle is improved, arcing is stabilized and the effectiveness of the cutting process is improved by equipping the torch with a ceramic collector whose inside surface is made in the form of a paraboloid with oblique openings uniformly placed around the electrode axis.

PERIODICAL:

Gornyy zhurnal, 1958, Nr 8, pp 58-60 (USSR)

ABSTRACT:

The water flow into the open pits of the asbestos ore mines of the Bazhenovskoye mestorozhdeniye Yuzhnogo rudoupravleniya (The Bazhenovo Deposits of the Yuzhnoye Administration of Mines) averages 500 cubic m./hour. Therefore, the question of organizing the water discharge is very important. The author describes various methods. These methods could be divided into 2 groups: 1) During the cutting of the ditch, the water is evacuated by a temporary pump, and only after cutting is completed is the permanent water discharge organized. 2) A drainage pit is excavated, and the permanent water discharge is installed

ABSTRACT:

In the urea synthesis in the liver of mammals one of its nitrogen atoms is supplied by ammonia whereas the other one is directly from the amino group of the L-aspartic acid (Refs 1-4). This last mentioned acid is formed in the organism by the transamination of the oxalacetic acid with the glutamic acid. In the glutamic acid the amine nitrogen of residual natural amino acids is, however, transformed under the influence of specific amino-ferases. The transamination reactions form an intermediate stage in the process of ammonia formation in the tissues of mammals, i.e. as a result of the transdesamination of the L-amino acids (Ref 4). It follows therefrom that the

suppression of the effect of the tissue aminoferases is bound to reduce the urea formation (Refs 3-6, 9, 10). In the experiments carried out at the Mc Henry School as well as in the laboratory of the institute mentioned in the Association the inhibition of the transamination reaction in the liver was always considerably imperfect, even in the case of an alimentary B₆-avitaminosis in an advanced stage. For this reason this problem was raised. The substance mentioned last in the title (INH) is known to inhibit considerably the action of the amino-ferases in vitro (Refs 11, 12), as well as in vivo (Ref 13). In the present experiments as well as in previous investigations (Ref 13), subtoxical doses of INH were repeatedly introduced into the animals, thereby causing the mentioned avitaminosis. However, since INH is quickly separated with urine (Ref 1), the author removed the kidneys of the experimental animals (white mice) in order to maintain a constant INH-concentration during the last experimental stage. Table 1 shows that after this operation i.e. after the suppression of the separation of the

products of nitrogen catabolism, the quantity of the non-protein-nitrogen increases progressively. This is caused mainly by urea accumulations in the tissues. The N of the amino-acids and the sum of the ammonia- and amide N increases inconsiderably. The increase of the total non-protein-nitrogen is reduced within 11 hours in mice into which INH was introduced. The urea formation is inhibited by 46%, compared to the control. Accumulations of free amino acid increased considerably, whereas ammonia- and amide N is only slightly higher than the control. It follows therefrom that the urea synthesis in the organism of the mouse *in vivo* is reduced rapidly by 53-64% in an acute B₆-avitaminosis (caused by INH), i.e. in agreement with the results of the inhibition of the transamination reactions in the liver homogenized mass *in vitro* (Ref 3). An imperfect suppression of the urea synthesis is caused by the utilization of the aspartic acid in the second stage of the

urea formation cycle (Ref 3). The experiments were carried out under the supervision of Professor A. Ye. Braunshteyn, Member AMS USSR (see Association). There are 2 figures, 1 table, and 18 references, 6 of which are Soviet.

TITLE: Changes in the quality of butter during cold storage in different wrappings

SOURCE: Kholodil'naya tekhnika, no. 4, 1965, 46-47

TOPIC TAGS: butter, cold storage, aluminum foil wrapping, food 44

ABSTRACT: The effect of different wrappings on the quality of butter stored in cold storage at -12 ~ -15°C was determined. Parchment wrapping (I) is compared with the combination of imitation parchment-aluminum foil wrapping (II). It was found that after a 12-month storage period the butter wrapped in I and II developed an outer nonedible layer amounting to 2.87 and 0.48% respectively. The effect of various wrappings on the taste and odor of butter is shown diagrammatically in Fig. 1 on the Enclosure. It is concluded that wrapping II leads to a saving of 15 rubles per ton of butter. Orig. art. has: 2 tables and 1 graph.
